**Keywords:** Hypothermia,  
postoperative period, analgesics,  
anesthesia recovery period.

## ABSTRACT

**Aims:** Postoperative hypothermia (POH) is a common but preventable adverse event. Our aim was to determine the incidence of POH and its effect on postoperative analgesic use in patients who underwent surgery in our hospital.

**Methods:** The files and anesthesia follow-up forms of 629 patients operated under general, neuraxial (spinal, epidural anesthesia), or regional anesthesia (peripheral nerve blocks) between March 2017 and May 2017 were reviewed retrospectively. Demographic data, anesthesia methods, surgical duration, post-anesthesia care unit recovery times, incidence of postoperative hypothermia, and postoperative analgesic use were evaluated.

**Results:** The incidence of POH was 22.1%. POH occurred most often following thoracic surgery (26.3%) and least often following urology operations (13.6%), ( $p=0.54$ ). Regarding type of anesthesia, POH occurred most frequently with regional anesthesia (peripheral nerve blocks) (32.2%), and least frequently with neuraxial anesthesia (spinal, epidural anesthesia), (14.9%), ( $p=0.01$ ). However, the rate of analgesic use was lower in patients with POH in the post-anesthesia care unit, although not statistically significant ( $p=0.14$ ).

**Conclusion:** POH is a frequently encountered problem in anesthesia practice, and the need for analgesia appears to be less in patients with POH in the post-anesthesia care unit.

## Introduction

Intraoperative and postoperative hypothermia provokes thermal discomfort, decreases drug metabolism, and prolongs recovery (1). It also causes serious complications, such as surgical wound infections, stroke, coagulopathy, and myocardial complications (2). Additionally, hypothermia causes vasoconstriction and impairment of the immune system, which may increase the incidence of perioperative wound infection in patients (3). Basic guidelines indicate that patients should be normothermic in the perioperative period, therefore, patients must be heated during this time (4).

Human body temperature is controlled by the hypothalamus in a hormonal manner as a result of stimulation from thermo-receptors (5). Induction of anesthesia and cool environment of operating rooms have the potential to impair the physiological mechanisms of thermoregulation (6). Postoperatively, an internal body temperature below 36 °C is defined as postoperative hypothermia (POH) (7). It has been shown that the incidence of POH is as high as 50–70% (8). The high rate of POH usually results from insufficient perioperative body temperature monitor-

ing and the lack of necessary attention to POH in many centers (9). Although there are many safe and inexpensive procedures for maintaining patient temperature, perioperative hypothermia is still widely observed.

POH contributes to an increased need for transfusion, delay in wound healing, and delay in patient recovery and discharge, which may subsequently lead to losses in labor and finances (2, 3). Inadequate pain management also adversely affects the quality of life of patients during and after hospitalization. However, there are very few studies that have investigated the changes in analgesia requirements in patients with POH, and no definite relationship between POH and postoperative pain has been established (10).

The aim of this study was to determine the incidence of POH and its effect on postoperative analgesic use in patients who underwent surgery in our hospital.

## Methods

This study was planned as a retrospective study. After approval of the study by the hospital ethics committee (2018/5,

18/105, date: 05.04.2018, Gülhane Training and Research Hospital), the files and anesthesia follow-up forms of patients who underwent surgery at our hospital between March 10, 2017 and May 10, 2017 were retrospectively reviewed. The study was conducted in accordance with the principles of the Declaration of Helsinki. The ethics committee waived the requirement for patient informed consent, because no patient re-contact was established for the study. Patients operated under general, neuraxial (spinal, epidural anesthesia), and regional (peripheral nerve blocks) anesthesia were included in the study. Intubated patients who were taken directly to the intensive care unit following surgery were excluded from the study. In addition, cases of cardiovascular and otorhinolaryngology surgery, which were not performed in the central operating rooms, were excluded from the study. Demographic data, the American Society of Anesthesiologists (ASA) physical status classification system scores, anesthesia methods, surgical duration, post-anesthesia care unit (PACU) recovery times, body temperature measured during admission to PACU, and analgesic drug information of the patients were obtained from the PACU follow-up forms. The patients were followed under standard monitoring (electrocardiography, noninvasive blood pressure, pulse oximeter) in PACU. Opioids or non-steroidal anti-inflammatory drugs were administered to patients with a visual analog scale (VAS) score of four and above in PACU, postoperatively. Patients with score of eight and above were discharged from the PACU unit according to the Aldrete discharge score. Aldrete discharge score is the most frequent used scoring system to evaluate discharge readiness from PACU. Body temperature measurements were performed using an infrared tympanic thermometer after the surgical procedures, while the follow up of the patients in the PACU (Genius 2TM, Covidien LLC, Mansfield, USA). Hypothermia was defined as a body temperature below 36 °C. Patients

with hypothermia were heated with external and internal heaters in PACU. After the patients' tympanic temperatures were increased from 36.0 °C and over, the patients were transferred to the clinic from PACU.

**Statistical Analysis:** After the data were transferred to a computer, analysis was performed using the Statistical Package for the Social Sciences (SPSS) 21.0 (SPSS Inc., Chicago, IL, USA). Data are presented as the number, percentage, mean, standard deviation, minimum, and maximum values. Mann-Whitney U-tests were used to compare continuous data from paired groups that were not normally distributed. A p value of <0.05 was considered to indicate statistical significance.

## Results

The incidence of POH was 22.1% in the study. POH occurred most often following thoracic surgery (26.3%) and least often following urology operations (13.6%), ( $p=0.54$ ). Regarding type of anesthesia, POH occurred most frequently with regional anesthesia (peripheral nerve blocks) (32.2%), and least frequently with neuraxial anesthesia (spinal, epidural anesthesia), (14.9%), ( $p=0.01$ ). However, the rate of analgesic use was lower in patients with POH in the post-anesthesia care unit, although not statistically significant ( $p=0.14$ ).

Of the 652 patients whose files and follow-up forms were scanned, 23 were excluded due to missing data. A total of 629 patients were included in the study. The rate of POH was found to be 22.1%. Demographic data, and operation times were similar, but PACU recovery times were significantly different between patients with and without POH (Table 1).

According to clinics, the highest POH rates were thoracic surgery 26.3%, general surgery 25.9% and neurosurgery clinic

**Table 1. Sociodemographic Data**

	Hypothermia (N:139) Mean ± SD	Normo-hyperthermia (N: 490) Mean ± SD	p
Sex			
Male	84 (23.9)	268 (76.1)	0.24
Female	55 (19.9)	222 (80.1)	
Age (Years)	38.14 ± 17.18	41.32 ± 20.02	0.09
PACU Recovery Time (Min)	39.36 ± 18.61	35.46 ± 11.86	0.02
Operation Time (Min)	94.83 ± 76.58	96.14 ± 67.27	0.84

**Table 2. Hypothermia Rates by Clinic**

Clinic	Hypothermia n (%)	Normo-hyperthermia n (%)	p
Neurosurgery	7 (25.9)	20 (74.1)	0.54
Pediatric Surgery	8 (17.8)	37 (82.2)	
General Surgery	44 (25.1)	131 (74.9)	
Thoracic Surgery	5 (26.3)	14 (73.7)	
Ophthalmic Surgery	5 (17.9)	23 (82.1)	
Obstetrics And Gynecology	22 (22.4)	76 (77.6)	
Orthopedics	29 (25.9)	83 (74.1)	
Plastic Surgery	8 (18.2)	36 (81.8)	
Urology	11(13.6)	70 (86.4)	
<b>Total</b>	<b>139 (22.1)</b>	<b>490 (77.9)</b>	

**Table 3. Hypothermia Rates by Anesthesia Method**

	Hypothermia n (%)	Normo-hyperthermia n (%)	p
General	91 (22.3)	317 (77.7)	0.01
Neuraxial (Spinal, Epidural Anesthesia)	20 (14.9)	114 (85.1)	
Regional (Peripheral Nerve Blocks)	28 (32.2)	59 (67.8)	
<b>Total</b>	<b>139 (22.1)</b>	<b>490 (77.9)</b>	

**Table 4. Analgesic Use in Patients With and Without POH**

	Hypothermia n (%)	Normo-hyperthermia n (%)	p
No Postoperative Analgesic Use	125 (89.9)	428 (87.3)	0.14
Postoperative Analgesic Use	14 (10.1)	62 (12.7)	
<b>Total</b>	<b>139 (22.1)</b>	<b>490 (77.9)</b>	

25.9%. The lowest POH ratio was urology with 13.6%. There was no statistically significant difference between the POH rates according to the clinic ( $P=0.54$ ) (Table 2).

According to anesthesia methods, POH rates were regional anesthesia 26.3%, general anesthesia 22.3% and neuraxial anesthesia 14.9%. There was a statistically significant relationship between the POH rate and anesthesia method ( $P=0.01$ ), (Table 3).

Analgesic using rate was 10.1% in patients with POH and 12.7% with normo-hyperthermia. Although statistically insignificant, there was a lower rate of analgesic use in patients with POH ( $P=0.14$ ), (Table 4).

## Discussion

In this study, we aimed to determine the incidence of POH and its effect on postoperative analgesic use in patients who underwent surgery. We observed that the incidence of POH was 22.1%. POH occurred most often following chest surgery and least often following urology operations. Regarding type of anesthesia, POH occurred most frequently with regional anesthesia, and least frequently with neuraxial anesthesia. Further, the rate of analgesic use was lower in patients with POH, although not statistically significant.

Although the incidence of POH is in the range of 50–70% in literature, we found an incidence of 22.1% in our study (8). According to a survey conducted by Torossian et al. (11) in 801 representative hospitals from 17 European countries, the incidence of POH was observed to be high during the perioperative period owing to the lack of body temperature monitoring and active heating systems. In our clinic, per the American Society of Anesthesiologists (ASA) protocol, all patients undergoing surgery underwent thermal monitoring during the perioperative period (12). In addition, electric heaters were used at the operating tables during surgery, serum and blood products were heated while infusing, and patients were treated with active heating systems in the PACU following surgery. As a result, the incidence of POH was much lower in our study than in the literature (8).

The prevention of perioperative hypothermia is important in Enhanced Recovery After Surgery (ERAS) protocols (13). The recovery and discharge times of patients with POH are known to be prolonged (3, 4). In our study, in accordance with the literature, we found significantly longer recovery times in patients

with POH than in those without. The implication is that POH extended the stay of patients in PACU and increased the workload of PACU staff.

There was no significant difference in the POH rate according to the clinic. However, POH was observed least commonly in patients who underwent surgery in the departments of urology, pediatrics, and ophthalmology, and most commonly in the thoracic surgery, orthopedic, and brain surgery clinics. This may be due to patient age and the width of the surgical site, as suggested in an earlier study (14). This indicates the need for more careful monitoring and close follow-up in these surgeries.

It is known that general, regional, and neuraxial anesthesia can disrupt heat thermoregulation and cause POH (11, 15). In our study, POH was found to be low in patients undergoing neuraxial anesthesia (14.9%), which is in accordance with the literature (16). In contrast, POH was more common in patients undergoing regional anesthesia (32.2%). We believe that this was due to the fact that body temperature monitoring was not taken into account during the time period in which regional blockade was conducted. Additionally, the provision of adequate sensory block for surgery and preventive measures were not taken into account for the prevention of heat loss. Patients were not heated during this time, and warming was started after the patient's arrival to the operation room. As a result, the incidence of POH was higher in patients with regional blockade.

Su et al. (17) showed increased tremor, energy consumption, and postoperative surgical incision pain levels in patients with POH. In a study by Benson et al. (14) pain intensity and opioid use were more common in patients with POH. However, in the study by Persson et al. (10) there was no relationship between POH and analgesic use. Conversely, we found a lower rate of analgesic use in patients with POH. Changes in neuronal physiology occur with a decrease in basal metabolism consumption and electrical activity in patients with hypothermia. This neuronal activity can produce nociceptive neuromodulation by reducing the transmission between the brain and spinal cord (18). Additionally, in one study, morphine clearance was significantly decreased in infants with hypothermia and elevated concentrations in blood were observed (19). Thus, the patients' need for analgesia is less in the PACU, as excretion of intra-operative analgesics is delayed and the blood levels of analgesics have not yet reduced. The implication is that POH causes a lower rate of pain in patients and decreases analgesic requirement in the PACU.

In this study, we evaluated the use of analgesics in PACU and observed that patients with POH had less analgesic needs. However, in order to determine whether this is good or bad, patients with POH should be followed up longer in the postoperative period and analgesic use should be evaluated particularly when they become normothermia.

This study had several limitations, including its retrospective design, lack of randomization, and lack of homogeneity of patients in terms of surgical and anesthetic techniques. The follow-up period of patients was limited to the PACU, and hence, comprehensive information about postoperative pain could not be obtained. In addition, some factors that may affect postoperative pain such as type of surgery and associated pain, hospital protocols, age and drug availability were not evaluated. Therefore, the relationship between POH and postoperative analgesic use may not be fully elucidated.

## Conclusions

In light of the findings obtained from the study, in order to decrease the incidence of POH, patients who undergo surgery should also undergo standard body temperature monitoring, and preventive measures for maintaining perioperative body temperature should be taken. Monitoring will not reduce the incidence but it will alert the practitioner of the occurrence and thereby allow appropriate intervention. Patient and serum heating systems should be used, and protocols should be established to prevent POH. Since the need for analgesia is less in patients with POH, dose adjustments should be performed to prevent excessive accumulation and overdose. Additionally, in order to understand the relationship between POH and postoperative pain, prospective, randomized trials with standard analgesia protocols are needed in patients undergoing the same type of surgery and anesthesia.
